## 1. Introduction

In this paper, the economy of Bangladesh is numerically specified within the framework of a social accounting matrix for the fiscal year 1993/94. The social accounting matrix has been developed around an input-output table for 1993/94 prepared by the Bangladesh Planning Commission and the Bangladesh Institute of Development Studies (BIDS) in 1998. Like all other standard input-output table, it shows the inter-relationships between economic activities in the economy in the given period (i.e. 1993/94). It traces the inter-industry transactions and maintains consistency between supply of and demand for commodities. The project social accounting matrix (SAM) may be considered as a generalisation of the input-output table which extends information beyond the structure of production to include: (i) distribution of value added generated by production activities; (ii) formation of household and institutional incomes; (iii) pattern of consumption, savings and investment; (iv) government revenue collection and associated expenditures and transactions; and (v) role of the foreign sector in the formation of additional incomes for households and institutions.

The social accounting matrix, developed in the paper, will serve two basic purposes: (a) comprehensive and consistent data system for descriptive analysis of the structure of the Bangladesh economy and (b) basis for macroeconomic modelling particularly the Computable General Equilibrium (CGE) model under the Monitoring Adjustment and Poverty (MAP) project. As a data framework, the SAM is a snapshot of the economy at a particular point in time (Pyatt and Thorbecke, 1976). In order to provide as comprehensive a picture of the structure of the economy as possible, the SAM approach has been used to bring together macroeconomic data (such as national accounts) and microeconomic data sets (such as household surveys), within a consistent framework<sup>1</sup>. The second purpose of the SAM is the provision of a macroeconomic data framework for policy modelling and development planning. The framework of the SAM can often help in establishing the sequence of interactions between economic agents and accounts that are being modelled.

As an analytical tool, the SAM provides an excellent framework for exploring both macroeconomic and multisectoral issues and is a useful starting point for more complex

---

<sup>1</sup> Large discrepancies are often revealed between these two sources. Whilst the conflicting sources must somehow be reconciled, often by choosing the more reliable ones, the construction of SAM forces attention to the root of their causes (King, 1985). A consequence of this confrontation between data source is the highlighting of priority areas for improving and extending the statistical data base of a country (Hayden and Round, 1982).

models (Robinson, 1989). In order to fulfil the above twin objectives, this paper provides the outline of the social accounting matrix for 1993/94. The paper specifies the major macroeconomic relations within the detailed framework and provides a consistent macroeconomic data set for policy modelling. The choice of the year 1993/94 as the benchmark is based on two grounds: (i) availability of most of the relevant data for the year and (ii) availability of a new and extended input-output table for 1993/94.

In order to depict a comprehensive picture, compilation of the SAM requires numerous data that are collected and compiled by different agencies/departments of the government. For example, national accounts and trade statistics are reported by the Bangladesh Bureau of Statistics (BBS), input-output tables are prepared by the Planning Commission (although such tables are seldom updated by different agencies as well as individuals)<sup>2</sup>, tax and non-tax revenue statistics are provided by the National Board of Revenue (NBR), industry statistics are reported by the Census of Manufacturing Industries (CMI), and household classification, income and expenditure patterns are presented by the Household Expenditure Surveys (HES). Since sectoral classification and statistics of these different sources are not readily compatible, the exercise needs various assumptions, extensive data manipulation, reconciliation and balancing in a way that can satisfactorily reveal the macroeconomic structure of the economy and depict the transactions between activities, factors, institutions, households and the rest of the world.

In particular, the social accounting matrix, presented in the paper, integrates the system of national accounts with input-output table and census of manufacturing industries data to show incomes by eight different categories of labour and distribution of operating surpluses between institutions such as government, corporations and households. It also bring together the national accounts, input-output and household expenditure survey data, within a consistent framework, for decomposition of 'households', distribution of household incomes, consumption expenditures and savings patterns. It also captures the flow of income from factors to the eight household groups, which are distinguished by occupational categories. The linkage between factoral and household distribution of incomes constitutes an important feature of the SAM, which is essential to examine distributional consequences of policy

---

<sup>2</sup> The World Bank updated the 1976/77 input-output table to derive a 35 sector table for 1984/85. The updated table was used in a general equilibrium revenue estimation model (1989). The Value Added Tax project, on the other hand, updated the 1976/77 table for 1988/89 in order to use in general equilibrium model to analyse revenue and equity aspects of the VAT system in Bangladesh (Mansur and Khondker, 1992). CIRDAP updated the 1986/87 augmented input-output table to 1992/93 as a data base for applied general equilibrium model (1996). Khondker (1996) updated an input-output table for 1988/89 using the 1986/87 table.

reforms. It also clearly shows the three basic macro balances that are used to close the economic system e.g., balance of trade, saving-investment balance, and government surplus.

The paper consists of three sections. Section II discusses various methods and procedures adopted to compile factor and institutional accounts of the SAM for 1993/94. Along with the steps and data used to compile different accounts of Social Accounting Matrix for 1993/94. The concluding observations are presented in section III.

## **2. The compilation of the social accounting matrix for 1993/94**

This section describes the compilation of a SAM for 1993/94. The accounting relations of the matrix bring together the structure of production, income generation by factors of production, distribution of income by institutions in return for factor services and savings and investment patterns. In particular, the matrix identifies the economic relations through four types of accounts: (i) production activity accounts for 79 sectors (described in the I-O table); (ii) nine factors of production with eight different types of labour and one capital; (iii) current account transactions between four main institutional agents; households and unincorporated capital, corporate enterprises, government and the rest of the world; and (iv) one consolidated capital account to capture the flows of savings and investment by institutions and sectors respectively. The methodology and statistical procedures adopted to compile the Social Accounting Matrix for Bangladesh are based primarily on a fully disaggregated Malaysian SAM, compiled by Pyatt, Round and Denes (1984)<sup>3</sup>.

### **2.1 The steps and data sources used in SAM compilation**

As mentioned above, the SAM is a generalisation of an Input-output table. A consistent Input-output table provides information for activity accounts, and different components of supply and demand. The following steps describe the compilation of a Social Accounting Matrix using the information of an Input-output table.

Usually a starting point for SAM compilation is the availability of a consistent Input-output table. Therefore, it is imperative to check the consistency of the available input-output

---

<sup>3</sup> With reference to the Malaysian SAM, Dhanani argues that 'besides its extensive disaggregation and coverage, the study offers a detailed discussion on the conceptual difficulties arising from the fundamental objective of a SAM, which is to integrate social statistics with major economic data under a common base, and on ways of dealing with numerous sources of data varying in quality and coverage,' (Dhanani, 1988)

table so that supplies equal demands for each activity and there are no leakages and injections into the system. A review of the input-output table for 1993/94 suggests a difference between total supply and total demand equal to the total trade and transport margin added to the C.I.F. value of imports. It appears that the difference arises due to improper use of imports in the construction of supply and use tables. To overcome the problem, the transport margins are added to I-O flow for the transport sector (70) and trade and other margins are added on to I-O flow of the trade sector (69). This adjustment envisages that these margins were originated from the domestic sources (as it should always be) and equilibrates the total supplies to total demand.

The number of activity classified in the I-O table always dictates the maximum number of activities of the production or activity accounts of a SAM. The I-O table prepared for 1993/94 comprises of 79 producing sectors or activities. Therefore, the activity account of the SAM includes 79 activities classified in the I-O table.

			<b>11 Activities</b>

A consistent I-O table provides information for different components of demand. These are government expenditures by 79 activities (which correspond to government accounts 97 in the SAM), exports by activities (rest of the world account 99 in the SAM), investment by 79 activities (capital account 100 in the SAM), and private consumption expenditures by activities and input demand by activities (production accounts 1 to 79 in the SAM). The components of demand are obtained directly from the consistent I-O table and are usually used in the SAM without any modifications or adjustments. On the other hand, the components of supply such as imports (rest of the world, 99), indirect taxes by activity (government accounts, 98), value-added by labour (factor accounts, 80 to 87), and capital (factor account, 88) are also obtained directly from the consistent Input-output table for 1993/94. Thus it is relevant to note that almost all the components of demand and supply are obtained from a consistent input-output table.

The vector of labour value added by 79 activities has been used as the control total to estimate the distribution of labour value added by activity and eight types of labour classified in the Social Accounting Matrix. The information derived from the Labour Force Survey (LFS) 1995/95 is used with this control total to estimate a matrix of value added by activities and by labour types. Similarly, the vector of private consumption expenditures has been used to calculate consumption expenditure by activities and eight types of households classified in the SAM. The information from the Household Expenditure Survey (HES) 1995/96 is used with this control total to estimate a matrix of sectoral consumption of goods and services and by household types.

Similarly, the vector of private consumption expenditure has been used to calculate consumption expenditure by activities and eight types of households classified in the SAM (see next for detailed discussion). Information obtained from Household Expenditure Survey 1995/96 is used with this control total to estimate a matrix of sectoral consumption of goods and services and by household type.

The estimated labour value added by labour types is then distributed among the eight household groups according to the observed (i.e. in HES and LFS) endowment of different types of labour in each of the eight household groups. Similarly the information of HES is used to distribute transfer income (i.e. government transfer and remittances) to eight types of household groups.

Information on ownership of industry by public sector, private sector and government observed in the Census of Manufacturing Industries (CMI) is used to distribute capital factor income between households, corporations and the government. National Account estimate of taxes, subsidies, current account deficit, budget deficit and other relevant

information is used to delineate the government account, corporate account and rest of the world account.

Savings by institutions (i.e. household, corporation, government and rest of the world) are derived residually to complete the accounts of the institutions as well as to close the system.

Table 2 describes the data sources and their usage in the compilation of the Social Accounting Matrix for 1993/94.

## 2.2. An outline of aggregate SAM of Bangladesh

For the purpose of exposition, the main economic relations are presented in an aggregated SAM for Bangladesh in Table 3. One hundred six sets of accounts contain four broad groups of accounts as follows; production (accounts 1-79), factors (accounts 80-88), institutions current accounts (accounts 89-99), and the consolidated capital account (account 100). The aggregated SAM satisfies the convention that the totals of corresponding rows and columns are equal and there is no leakage and injection into the system. Therefore, the aggregated SAM is a squared matrix. The matrix presentation allows each transaction in the accounts to be represented by a single cell in the matrix<sup>4</sup>. The main objective of presenting the aggregated matrix is to summarise and to show the circular flow in the Bangladesh economy. It also provides a useful basis for describing the basic structure of accounts upon which subsequent discussion follows (Pyatt and Round, 1985). The disaggregated and detailed SAM is presented in Appendix A3.

## 2.3 Derivation of labour income and operating surplus

It is observed from the aggregated SAM that the value added at factor cost (Taka 1,201,715 million) is decomposed into labour income (Taka 603,474 million) and operating surplus (Taka 573,921 million). The I-O table shows the total as well as the sectoral breakdown of the gross value added, value added at factor costs and domestic indirect taxes. However, in the aggregated SAM all types of indirect taxes are combined for the purpose of presentation. The total indirect tax of Taka 89,799 million comprises of domestic indirect tax of Taka 24,319 million and import duty and value added tax of Taka 65,480 million. To split the sectoral value added at factor cost ( $V_i$ ) into labour income and operating surplus, sectoral labour income by factors ( $L_i$ ) is estimated by adopting the procedure as follows: (i) the employment coefficient matrix of 1986/87 I-O table and the vector of labour employment for 1993/94 derived from different published sources are used to derive the estimates of sectoral employment by categories for 1993/94. The estimation procedure may be expressed as:

$$\Omega_{il} = \Omega'_{il} \cdot T_l$$

---

<sup>4</sup> A SAM is a single entry system because the transactions are shown once only as elements of the matrix, so that the element (i, j) is the expenditure from account j which is received by account i. In contrast to the double-entry system, the accounts have to be 'fully articulated' in a SAM. In other words, both the origin and destination of each transaction (in terms of the accounts of the system) have to be specified. A display of origin and destination of each set of transactions can greatly facilitate understanding of inter-relationships between various parts of the macro economy (Hayden and Round, 1982).

Table 3: Aggregated social accounting matrix for Bangladesh, 1993/94

	<i>Factor AC</i>			<i>Institutions AC</i>				Capital AC (100)	Total Demand
	Production Activity AC (1..79)	Labour (80..87)	Capital (88)	Household AC (89..96)	Government (97)	Corporate AC (98)	Rest of the World AC (99)

Labour (80..87)	Capital Value- added 579,617	0	0	0	0	0	0	0	579,617
Capital (88)	0	HH Income from Labour 603,474	HH Income From Capital 552,338	Income Tax 5,500	Transfer to HH 38,489	0	Remittance 48,139	0	1,242,440
Household AC (89..96)	0	0	1,926	Income Tax 5,500	0	Corporate Tax 2,599	0	0	99,824
Government AC (97)	Indirect Tax 89,799	0	25,353	0	0	0	0	0	25,353
Corporate AC (98)	0	0	0	0	0	0	0	0	158,857
Rest of the World (99)	Imports 158,857	0	0	93,601	4,198	22,754	11,979	0	132,532
Capital (100)	0	0	0	1,242,440	99,824	25,353	158,857	132,532	
Total Supply	2,799,640	603,474	579,616						

where,  $\Omega_{it}$  is the estimated employment matrix for 1993/94,  $\Omega'_{it}$  denotes employment coefficient matrix of 1986/87 and  $T_i$  is the vector of employment by labour categories for 1993/94; (ii) the value added share by major occupational categories of labour are based on available data on wages and productivity of labour. The wages of different categories of labour engaged in agriculture sector are based on various reports and surveys. The labour share of various industries are adopted from available Census of Manufacturing Industries (CMI) reports and information collected from other sources.

The labour share for construction sectors are estimated on the basis of wages by skills of construction workers. The wages of various categories of labour of electricity and gas sectors are obtained from relevant sources. The wages by occupational groups in health, education and public administration sectors are compiled from the budget and other documents. The wages of different categories of labour in other services sectors are based on available reports and information collected from establishments and institutions (CIRDAP, 1996). The compiled vector of sectoral wages for 1993/94 and estimated employment matrix of 1993/94 are then used together to derive the sectoral labour income by factors for 1993/94. The derivation of sectoral labour income by factors is shown as:

$$L_{it} = \Omega_{it} \cdot W_{it}$$

where,  $W_{it}$  is a vector of sectoral wages for 1993/94. The sectoral labour income is then deducted from sectoral value added at factor costs to derive sectoral operating surplus ( $K_i$ ) residually. The derivation of operating surplus may be expressed as:

$$K_i = V_i - \sum_i L_{it}$$

The distribution of sectoral value added into sectoral labour income and operating surplus is shown in Table 4.

Table 4: Distribution of value added at factor cost, 1993/94

(In million Taka)

No.	Sectors	Value added at Factor cost 1	Compensation of employees 2	Operating surplus 3=2-1

## 2.4 Returns to corporate, unincorporated and government capital

The estimated returns to capital or operating surpluses stand at Taka 579,616 million. This consists of returns to unincorporated capital, corporate capital and government capital. The decomposition of operating surplus is depicted in the aggregated SAM where unincorporated returns are Taka 516,821 million, corporate returns are Taka 25,352 million and government returns are Taka 37,443 million. Following methods are adopted to disaggregate the sectoral operating surpluses.

It is assumed that no operating surplus originates in the agricultural sectors, forestry, construction, and trade and transport sectors. Therefore, all returns to capital or operating surpluses in these four sectors are assigned to unincorporated capital. The operating surplus

generated by the manufacturing sectors consists of returns to unincorporated, government and corporate capitals since industries are owned by individuals, government and private or corporate firms<sup>5</sup>. The information from CMI is used to distribute the total manufacturing operating surplus. The CMI shows the breakdown of consolidated manufacturing operating surplus by government, private and individual firms. The CMI also provides the breakdown of the manufacturing operating surpluses by government and private firms at three-digit industry groups. These information are aggregated according to the I-O sector classification to derive the distribution of manufacturing operating surplus by government and private firms for the eight manufacturing sectors. The estimated sectoral operating surpluses of private corporation are further disaggregated into operating surpluses by individual and private corporations, following assumptions and data manipulations.

On the other hand, some of the sectors such as energy, health, education, and public administration are mostly controlled by the government. So, the operating surpluses of these sectors are assigned to government capital. The housing sector, which consists of urban and rural house-building, is dominated by individuals and small firms as is the 'miscellaneous service' sector, which includes professional service of doctors, lawyers, accountants, consultants and other professional groups. Thus, the operating surpluses of these two sectors are treated as accruing to as unincorporated capital. The banking and insurance sectors are controlled both by corporate firms and the government. The operating surpluses of banking and insurance sectors are distributed between government and corporate capital on the basis of published information.

The sectoral distribution of operating surpluses between unincorporated, corporate and government capital is shown in Table 5.

---

<sup>5</sup> In the 'CMI report' no distinctions are made between private and public limited corporations and both private and public limited corporations are treated as private or corporate firms. A similar treatment is retained.

## 2.5 Corporate profits, taxes, and savings

Total corporate tax collection in 1993/94 was Taka 2,599 million (Statistical Year Book of Bangladesh, 1997). The corporate tax is levied on profits of the corporate establishments. It is observed that corporate profit originated in 19 sectors and the total corporate profit is Taka 25,352 million (Table 6). Since information on the sectoral breakdown of total corporate tax is not available, the proportions of corporate profit of each of the 19 sectors with respect to total corporate profit are used to distribute the total corporate tax among these 19 sectors. The sectoral corporate savings are derived by deducting sectoral corporate tax payments from sectoral profits (Table 6).

Table 6: Corporate profits, taxes and savings, 1993/94

## 2.6 Government account

The collection of government revenue involves tax and non-tax sources. The main sources of tax revenue are: (i) indirect taxes on imports and domestic production (Taka 89,799 million) and (ii) direct taxes in the form of corporate and income taxes (Taka 8,099 million). The main sources of non-tax revenue are incomes from government owned corporations, financial institutions and other sources. The total government income is reported at Taka 135,341 million in 1993/94. On the other hand, total government expenditure is Taka 131,143 million (Statistical Yearbook of Bangladesh, 1997). Total government expenditure includes government transfer to household groups amounting to Taka 74,006 million. The government transfer to household consists of targeted expenditure programme, food subsidy and expenditure on social sectors such as health, education and housing. Total government savings is derived residually which is difference between total government income and total government expenditure.

## 2.7 Household classification and accounts

An important feature of the SAM is the decomposition of the households into eight groups. The household groups differ with respect to employment status, income levels and expenditure patterns. Pyatt and Thorbecke (1976) suggest location, sociological and wealth

criteria to classify household groups<sup>6</sup>. However, the classification of households depends on availability of information and the issues that need to be addressed. For example, since information on income levels are readily available, households are seldom classified by levels of income. Indeed, grouping of households by income levels is an informative approach to describe income distribution issues at a point in time. However, if the purpose is to provide a basis for diagnosis and policy formulation, then the grouping criteria should correspond to constituencies that can be influenced differentially by means of policy. It is argued that household groups based on income levels alone cannot be legislated for as such, on the ground that household units are mobile between these groups, there is a need to identify target households with respect to observable characteristics (Pyatt and Thorbecke, 1976).

In the present SAM, socio economic groups based on occupational status of the principal earner of the households has been used to classify households. This criterion is likely to capture differences in employment practice, life style and assets among the household types which in turn have different relationships with factors markets, as noticed in the SAM for other countries (e.g., for Malaysia, see Pyatt, Round and Denes, 1984). The virtue of this criterion is that two households who have similar income levels, may be significantly different in other aspects, especially according to living standards and patterns of consumption expenditure. According to the above two criteria, six different household groups are distinguished and the households are divided into eight categories.

The main source of information for the above disaggregation of household groups is the household distribution from the 1995/96 Household Expenditure Survey (HES) of the Bangladesh Bureau of Statistics. Usually, the HES provides a breakdown of earners by employment status of head of households and employment status of other than head of households according to 16 income groups. Although information on income and expenditure patterns by 31 occupational groups are collected under the HES, these are not reported in published statistics. The unpublished information collected from the source, have been compiled to generate two matrices to: (i) distribute consumption expenditure by 31 occupational households and 16 income groups in terms of HES commodity classification; (ii) allocate incomes of 31 occupational household groups by 44 major sources.

Observing the similarities in the employment characteristics, the 31 household groups are then reclassified into eight occupational household groups. The distribution of the households into eight groups is provided in Table 7.

---

<sup>6</sup> For instance, the location criterion which distinguishes a household as urban or rural is useful since it captures many aspects of duality. Depending on this distinction, individuals with otherwise similar characteristics are likely to be paid different wages, have different job opportunities and employment expectations and generally be subject to different sets of parameters in their socio-economic behaviour (Pyatt et al, 1984).

### 2.7.1 Distribution of labour income among households

The total labour income generated by the eight labour categories is Taka 603,474 million. The households are the recipient of this total labour income. The 1993/94 HES, unpublished tables provide information on sources of income by 31 occupational household groups. These include labour income from agriculture, non-agriculture, service, administrative and professional, production and transport activities. The tables also provide capital income from various heads such as bank deposits, insured money, dividend, and other assets. In addition, household income from remittances and transfers from other household groups are reported. In line with the nine I-O factor classification and observed HES and I-O classifications, the HES sources are regrouped into nine factors. Finally, the derived household to factor income matrix is adjusted so that household's income from each of these nine factors corresponds to the factors reported earlier.

### 2.7.2 Household income from other sources

Besides labour and unincorporated capital incomes, households also receive incomes from other sources, namely remittances or factor incomes from abroad, and government transfers in the form of pension. The information of the HES unpublished tables on income sources of households are used to distribute remittances among the eight households.

The pension income is very limited in Bangladesh. Persons who are employed in government, semi-government and autonomous establishments are eligible for pension income. This is a transfer of resources from government to persons or households in accordance to their contributions made during their working years. Hence pension income is distributed only among the three household groups (e.g., professional, service, and skilled workers) according to their shares in total labour income.

### 2.7.3 Derivation of household expenditure on goods and services

The aggregated I-O table depicts sectoral breakdown of consumption expenditure on goods and services. The HES unpublished tables, on the other hand, provide detailed breakdown of expenditure by 31 occupational household groups and HES commodities. In particular, the HES identifies 40 sectors which are somewhat different than the I-O sector classification. So, the HES sectors are mapped to the I-O sectors according to the mapping scheme used by Mansur and Khondker (Mansur and Khondker, 1992). However, sectoral consumption from HES estimates are found to be different from the I-O sectoral consumption estimates. Therefore, sectoral consumption expenditures by the 31 groups are adjusted using sectoral scaling factors so that the sectoral consumption corresponds to the I-O sectoral consumption estimates. The consumption expenditures by I-O sectors and the 31 household groups are converted into sectoral consumption expenditure by the eight household groups using Table

7. The distribution of consumption expenditures by the eight household groups are shown in Appendix A<sub>2</sub>.

#### 2.7.4 Total receipts, outlays and savings by households

Personal savings by the eight household groups are derived in this section. The personal savings of each household group is calculated residually by deducting household's total outlays and income taxes from household's total receipts. The total income tax collection is Taka 5,500 million in 1993/94. No information is available to determine the amount of income tax paid by each household group. It has been assumed that only three groups (e.g., professional, service, and skilled workers) operating in the formal sector are eligible for income tax payment. Hence total income tax is distributed among these household groups according to their shares in total income. The total personal saving is estimated at Taka 93,605 million. Total receipts, outlays and savings by the household groups are shown in Table 11.

### 3. Conclusion

This section discusses the salient features of the numerical specification of the Bangladesh economy within the framework of an input-output table and a social accounting matrix. The main features of this exercise are summarised as follows:

- The paper provides the compilation of a SAM as an outcome of integration of different data sources and the input-output table. The exercise provides a quantitative description of the processes of production, income generation by factors of production, distribution of income by institutions and savings and investment patterns within a detailed framework. The present SAM provides a useful framework for exploring both macroeconomic and multisectoral issues in Bangladesh which are not readily observable from different disconcerted data sources.
- The SAM integrates numerous data that are collected and compiled by different agencies and departments of the government. Since sectoral classification and statistics of these different sources are not readily compatible, the exercise adopted various assumptions, extensive data manipulation, reconciliation and balancing factors to compile the SAM. The methodology and statistical procedures used to compile the SAM are discussed in detail. The exercise thus provides a framework to generate and extend future social accounting matrices in Bangladesh.
- The exercise highlights the importance of SAM as a useful aid to policy analysis which can focus on socio-economic linkages in the economy and on simulation of policy reforms using both SAM-based fixed-price models and flex price computable general equilibrium models. The present SAM is also suitable for income distribution analysis as it shows the linkages between factoral distribution of income by nine factors and personal distribution of income by the six household groups.

## **C I R D A P**

The Centre on Integrated Rural Development for Asia and the Pacific (CIRDAP) is a regional, inter-governmental, autonomous institution, established in July 1979 at the initiative of the countries of the Asia-Pacific Region and the Food and Agriculture Organization (FAO) of the United Nations with support from several other UN bodies and donors. Its member countries include Afghanistan, Bangladesh (Host State), India, Indonesia, Lao PDR, Malaysia, Myanmar, Nepal, Pakistan, the Philippines, Sri Lanka, Thailand and Vietnam.

The main objectives of CIRDAP are to (i) assist national action; (ii) promote regional cooperation, and (iii) act as a servicing institution for its member countries for promotion of integrated rural development through research, action research, pilot project, training and information dissemination. Amelioration of rural poverty in the Asia-Pacific region has been the prime concern of CIRDAP. The Centre is committed to the WCARRD Follow-up Programmes. The programme priorities of CIRDAP are set under four areas of concern: (1) agrarian development; (2) institutional/infrastructural development; (3) resource development including human resources; and (4) employment.

Operating through designated Contact Ministries and Link Institutions in member countries, CIRDAP promotes technical cooperation among nations of the region. It plays a supplementary and reinforcing role in supporting and furthering the effectiveness of integrated rural development programmes in the Asia-Pacific region.
